

ABSTRACT of the DISCLOSURE.

On a mobile rest plane on which tiles are translated in a predetermined direction, the following operate: a matrix-bearing cylinder, mobile in rotation about an axis thereof, and at least a doctor predisposed to operate contactingly with an external surface of the cylinder. The apparatus
5 comprises: a vertically-developing frame; a first slide constrained on the vertical frame and slidable vertically with respect thereto; the matrix-bearing cylinder being supported on the first slide, together with organs for supporting the matrix-bearing cylinder and organs for controlling rotation thereof about a rotation axis thereof; a second slide, with at least one doctor
10 being supported thereon, together with organs for supporting the doctor and organs for controlling movements thereof, is constrained on the frame and can slide vertically with respect thereto. An electrically-activated maneuvering screw produces relative positioning of the first slide and the second slide and positioning of the slides with respect to the vertically-
15 developing frame.
